

Is Drawing from the State ‘State of the Art’?: A Review of Organised Crime Research Data Collection and Analysis, 2004-2018

Corresponding author: Dr James Windle, Lecturer in Criminology, Department of Sociology, University College Cork, Ireland, james.windle@ucc.ie

2nd author: Professor Andrew Silke, Chair in Terrorism, Risk and Resilience, Cranfield University, A.Silke@cranfield.ac.uk

Abstract

This paper presents a systematic review of organised crime data collection and analysis methods. It did this by reviewing all papers published in Trends in Organized Crime and Global Crime between 2004 and 2018 (N = 463). The review identified a number of key weaknesses. First, organised crime research is dominated by secondary data analysis of open-access documents, and documents are seldom subjected to the same principles guiding primary data collection methods. Second, data analysis lacked balance with a distinct lack of inferential statistical analysis. Third, there was a significant absence of victim or offender voices with an overreliance on data from state bodies and the media. The paper concludes that organised crime, as field of research, appears unbalanced by reliance upon a small number of methods and sources. Rebalancing the field requires more organised crime researchers to speak to offenders and victims, employ greater use of statistical analysis and tighten our methodologies.

Is Drawing from the State ‘State of the Art’?: A Review of Organised Crime Research Data Collection and Analysis, 2004-2018

Abstract

This paper presents a systematic review of organised crime data collection and analysis methods. It did this by reviewing all papers published in *Trends in Organized Crime* and *Global Crime* between 2004 and 2018 (N = 463). The review identified a number of key weaknesses. First, organised crime research is dominated by secondary data analysis of open-access documents, and documents are seldom subjected to the same principles guiding primary data collection methods. Second, data analysis lacked balance with a distinct lack of inferential statistical analysis. Third, there was a significant absence of victim or offender voices with an overreliance on data from state bodies and the media. The paper concludes that organised crime, as field of research, appears unbalanced by reliance upon a small number of methods and sources. Rebalancing the field requires more organised crime researchers to speak to offenders and victims, employ greater use of statistical analysis and tighten our methodologies.

Introduction

In 1989, Cyrille Fijnaut (1989:75) contrasted the ‘very small’ academic interest in organised crime with an increasing state and popular concern. The academic study of organised crime has, however, expanded considerably since the end of the Cold War: There now exist dedicated organised crime textbooks and handbooks, journals and research groups. Many undergraduate and postgraduate social science degrees have organised crime modules and there are a small number of postgraduate programmes dedicated solely to organised crime and more combined with terrorism studies.

While the field is growing, it has had very few systematic health checks. In the UK, when you turn 40, you receive an invitation from the British National Health Service to attend a routine health check-up to ensure your aging body is functioning as it should. The academic study of organised crime is almost 90 years old, if we start with Landesco (1929) and Thrasher (1927), yet its health has yet to be reviewed.

The aim of this paper is to assess organised crime research by systematically reviewing the data collection and analysis methods employed in articles published in the two main organised crime dedicated academic journals. This technique has a long history in terrorism studies

(Schuurman 2018; Author2 2000, 2004, 2006) – a field which shares certain characteristics and methodological challenges (Author1 at al. 2018) – but has yet to be explored in organised crime studies.

Organised crime research

The main function of research is to create new knowledge: to provide new insights and, greater awareness and understanding of a phenomenon. According to Colin Robson (1993), this research-generated knowledge can be categorised as: exploratory, descriptive or explanatory. Interpretative can be added as a fourth type. Exploratory research may be concerned with basic questions, often trying to understand what is happening by researching an emerging issue with little existing knowledgebase. It may also explore new data collection methods or sources. The next level attempts to describe what is happening, or what has happened, including who is involved and how the phenomena might work. Exploratory and descriptive research does not move beyond the descriptive to explain causation nor interpret meaning sufficiently. Exploratory and descriptive research often employs qualitative research methods, often relying on smaller case studies. The methods may not be overly concerned with issues of reliability and validity, as the primary importance is to set the scene. That is, to identify what may be the main forces at work. A second function may be to lay down a useful ‘mark in the sand’ for research grant applications or larger studies.

Explanatory research attempts to identify causes and sometimes to forecast what might happen in the future, often building on foundations set by more exploratory and descriptive studies. At this final level, the research methods used are more rigorous and more intensive than at the previous stages, partly because the researcher must address greater concerns that findings are clearly reliable and valid (Author2 2000). Interpretative understanding also goes beyond the descriptive, however, instead of seeking causes of a phenomena, the research will seek to understand the meaning of the action within a particular context (Bottoms, 2010). While explanatory research is often identified as quantitative, and interpretative as ethnographic, well designed and executed qualitative research can be explanatory and vice versa.

Klaus Von Lampe (2017:45), a leading expert on organised crime and former editor of *Trends in Organised Crime*, acknowledges that while a large body of ‘conceptually and theoretically ambitious research’ exists, ‘much of contemporary research on organized crime is primarily descriptive’. Von Lampe’s statement came 40 years after Donald Creasy (1967:102) noted that ‘social scientists have tended to write about organized crime only in descriptive terms’.

1 Research is an iterative endeavour. The aim of our field should be progression from one level
2 of understanding to the next: Exploratory and descriptive studies are valuable for their capacity
3 to inform future explanatory and interpretive works. All fields, however, require a significant
4 number of studies at the explanatory level. Subject areas which fail to make the transition into
5 explanatory are left with gaps in their knowledgebase, a fatal uncertainty over the causes of
6 events and what are the truly significant factors at work, and may be constrained by a failure
7 to predict future events. Such a field may, however, appear relatively active, especially in an
8 applied field such as organised crime. Research that has a real-world focus will nearly always
9 have outlets for exploratory and descriptive research.
10

11 It is acknowledged that organised crime can be a difficult topic to research. Cressey's (1967)
12 early observations on researching organised crime remains, more or less, intact:
13

14 The secrecy of participants, the confidentiality of materials collected by
15 investigative agencies, and the filters or screens on the perceptive apparatus
16 of information's and investigators pose serious methodological problems for
17 the social scientist who would change the state of knowledge about organized
18 crime (101).
19

20 To this, one could add that researching organised crime can be costly, time consuming,
21 potentially risky and present ethical barriers (see Gallhier and Cain 1974; Hobbs 2000; von
22 Lampe 2017; Author1 2018). At the very least it can be difficult to convince risk adverse
23 research ethics committees that the research will not harm the researcher, participant or
24 university.
25

26 William Chambliss (1975:36), however, suggested that criminology and sociology suffer a
27 'myopic research vision' about the possibilities of collecting data on organised crime. Drawing
28 from his own ethnographic research experience, he argued that such data is 'more available
29 than we usually think. All we really have to do is get out of our offices and onto the streets'
30 (39).¹ While von Lampe (2017:50) simply highlights that previous research endeavours
31

32 ¹ Chambliss's research into organised crime in Seattle was not risk free: he was threatened
33 with law suits and violence (Inderbitzin and Boyd et al. 2010) while his objectors tried
34 unsuccessfully to engineer precarious situations with which to blackmail him (Chambliss
35 1978). Serious violence against researchers is rare, although the risk of harm, kidnap and
36 extortion is higher in certain regions of the world, and a very small number of researchers

1 demonstrate that ‘there are no insurmountable obstacles for examining’ organised crime.
2 Research may often need just a little more patience, planning, foresight and social capital than
3 less clandestine and risky phenomena (see Felbab-Brown 2014; Hobbs 2000; von Lampe
4 2012).

5
6
7 Von Lampe (2002) proposed three problems haunting organised crime research. The first and
8 second are interlinked: (1) the problem of definition and (2) conceiving organised crime as a
9 distinct field. Neither will be discussed at length here, but conceptual confusion continues to
10 mire the study of organised crime. Researchers cannot agree on what is meant by organised
11 crime, organised criminal or organised crime group. Varese’s (2010) position that organised
12 crime should be split into three categories (enterprise crime, organised crime groups and
13 mafias) based upon governance of markets is not only a strong one but also demonstrates the
14 breadth of the organised crime field: research subjects have ranged from solitary dodgy car
15 dealers to well organised criminal fraternities performing quasi-state functions. Furthermore,
16 there can be a fuzzy overlap between organised crime and other fields of study, notable street
17 gangs, corporate crime and terrorism. It may, however, be that ‘organized crime’ is best thought
18 of as representing an ‘open, multi-dimensional and dynamic concept to mark out a field of
19 study’ (von Lampe 2002;195). In practice, the parameters of this field may well be set by the
20 very existence of *Trends in Organized Crime*, *Global Crime* and the various organised crime
21 textbooks. This article is not, however, concerned with conceptual debates, but rather research
22 activity.

23
24
25 The third problem is that media, public and professional perceptions of organised crime –
26 including ‘established facts’ and ‘common knowledge’- are often challenged by empirical
27 evidence (von Lampe 2002; also Hobbs and Antonopoulos 2014). Indeed, a number of studies
28 have shown how offenders and criminal justice practitioners perceive particular phenomenon
29 quite differently (Decker and Kempf-Leonard 1991; Author1& 2016). This presents the
30 researcher with two problems. First, policy makers, practitioners, the media and public may
31 not want to hear alternative evidence and analysis which challenges their view (or agenda).
32 This may lessen some researchers’ prospects of securing funding and having meaningful
33 impact outside of academia. Second, it highlights the difficult issue of relying on data drawn

1 from the state and media, a potential problem which will be returned to in the results section
2 below.

3
4 The current paper is concerned with how data on organised crime is collected and analysed.
5 The practical nature of research on organised crime. The ultimate aim of research is to arrive
6 at a level of knowledge and understanding which allows us to explain why particular events
7 have happened and, to predict the emergence and outcome of similar events in the future. It
8 will be argued below that organised crime research has failed to attain such a level of
9 knowledge. This article will examine what measure of responsibility for this failure rests with
10 the activities of the research community itself, particularly in how it gathers data and in the
11 level of analysis to which it submits harvested data. We do not argue that any one method is
12 superior, but rather that for a field to thrive it should be generating new data, explaining rather
13 than describing the phenomena under investigation and employing a range of methods.

22 **Methodology**

23
24
25 There are two primary ways of assessing the state of the art of organised crime studies: sending
26 a questionnaire survey to active researchers, a method which has previously been employed in
27 terrorism studies (see Schmid and Jongman 1988). A clearer method is to examine the
28 published literature produced by researchers. This method has previously been employed by
29 one of the authors to evaluate terrorism research (Author2 2000, 2004; see also Schuurman
30 2018). Only one organized crime study has employed a somewhat comparable method: over
31 40 years ago, John F. Gallhier and James A. Cain (1974) reviewed 102 Criminology textbooks
32 (1950-1972) to identify sources cited.
33
34
35
36
37
38
39

40 The review of published research is feasible because there are currently two well-established
41 peer-reviewed academic journals dedicated to primarily publishing research on organised
42 crime: *Trends in Organized Crime* and *Global Crime*.² They have different publishers, separate
43 editorial teams and largely separate editorial boards (though with some overlap). While we
44 acknowledge much organized crime research is published outside of these two journals, taken
45 together they provide a reasonably balanced impression of research activity in the field during
46 the period under review. Peer-reviewed journals are considered particularly important as the
47
48
49
50
51
52
53
54

55
56 ² While *Crime, Law and Social Change* has traditionally had a major focus on organised
57 crime, it was felt that the journals focus has drifted away from organised crime in recent
58 years to an extent that it may no longer be considered a specialised journal.
59
60
61
62
63
64
65

1 peer review process acts as an important quality check to ensure that the published work meets
2 minimum standards in terms of scientific quality and reliability. While peer review has its
3 flaws, no alternative system has been developed so far which can exceed or even match peer
4 review in terms of maintaining the quality of scientific literature. As a result both national
5 research assessment frameworks and academic employment and tenure panels place a heavy
6 emphasis on research publications in peer-reviewed journals, generally weighting them heavier
7 than any other research outputs.
8

9
10
11 In order to better understand the current trends in research activity in the field for the past 14
12 years, this article presents the results of a review of the published output of the two primary
13 journals in the area between 2004–2018. Each article published in the two journals for this
14 period was reviewed (N = 463), this included introductions to special issues and book review
15 essays but excluded erratum's, book reviews and extracts from official reports. We
16 acknowledge that some may have issue with the inclusion of book review essays and
17 introductions to special issues, however, these articles tend to provide new knowledge and are
18 often cited by other authors.
19

20
21 Following the categories in Author2's (2000) review of terrorism research, the following data
22 was recorded for each article: full citation; first author; second author; first author's institution;
23 types of data source; data collection method; whether paper collected primary data³ or relied
24 solely on a secondary document analysis; type (if any) of statistical analysis conducted. In
25 addition to Author2's original categories, we also collected data on the number of research
26 participants and whether the paper included a methodology.
27

28
29 Data was collected between May 2017 and May 2018, by the first author. The following
30 procedure was followed for each article: The title, abstract and key words were initially read.
31 The methodology (if available) was then read and the paper was skimmed for any tables or
32 charts which would indicate statistical analysis. The reference list was then scrolled through to
33

³ Primary data is here defined as defined as data collected 'first hand for the specific purpose
of addressing the' research question, as opposed to secondary data which is collected 'by
other peoples or other agencies with other purposes in mind' (Jupp 2001:33)

1 identify sources used. If methods remained unclear, then key words were used to search the
2 article.⁴
3

4 We recognise that categorising data collection methods can be subjective and another
5 researcher reviewing these 463 articles may have categorised some methods differently. As
6 with Bart Schuurman (2018:5) we utilised a ‘low inclusion threshold’ in order to avoid making
7 subjective judgements about the quality of methods. For example, participant observation
8 ranged from brief mentions of field work to in-depth ethnographies, while a pie chart was
9 sufficient for the descriptive statistics box to be ticked in the dataset.
10
11
12
13
14

15 *Limitations*

16 Organised crime is a large and diverse field and we acknowledge that the two journals do not
17 represent the entirety of organized crime research. Many of the most influential studies on
18 organized crime have been published in other academic journals, edited volumes, monographs
19 and research reports. The two journals do, however, represent a good sample of the literature.
20 Most researchers with a significant interest in organised crime publish in *Trends in Organized*
21 *Crime* and/or *Global Crime* at some point in their career. Furthermore, identifying and
22 reviewing all published organised crime research would be an unmanageable task which would
23 involve a degree of subjectivity in choosing what is and what is not organised crime. Here the
24 parameters of organised crime have been set by the editors and reviewers of the two journals.

37 **Results**

38 Figure 1 and 2 provide breakdowns of the data collection methodologies and data sources
39 currently being used by published researchers. A minor cause for concern with Figure 1
40 involves the finding that 1.30 percent (N = 6) of articles published in the journals give no
41 indication for the source of their information. Most of these articles were written by criminal
42 justice or security practitioners, and the assumption is that the article is based on their own
43 personal experience. It is, however, impossible to evaluate such articles in terms of reliability
44 and validity, and as a result their value in research terms is contentious. This said, this type of
45 paper became increasingly less common during the period under review.

Document analysis

Figures 1 and 2 clearly show that research on organised crime is dominated by secondary data analysis of open-access documents. Figure 1 shows that 64.1 percent (N = 297) of all research on organised crime is based solely on data gathered from academic literature, the media, state or non-governmental published documents.⁵ Discouragingly, 56.5 percent (N = 262) of papers failed to include a methodology. Organised crime studies may legitimately be regarded as an interdisciplinary field of research and different academic disciplines can vary in terms of standards for the presentation of new research. Nevertheless, the lack of a methodology in so many papers raises concerns about the quality and reliability of much research. Given the heavy reliance on document analysis, important concerns may be raised over: the lack of detail on how documents were found, combined with an absence of discussion on the documents' reliability and validity or assessment of the potential limitations to their use. Ultimately, as John Scott (1990) argues, documents should be subjected to the same principles guiding primary data collection.

Figure 2 shows that 96.7 percent (N = 448) of all published articles included at least one academic reference. The next most used source was open-access government documents (60 percent, N = 278) followed by, media and news sources (41.4 percent, N = 192). Conversely, the most common primary source - interviews with government sources — was used in just 17.9 percent (N = 83) of published articles.

These figures seem to indicate a field overly dominated by 'integrators of [the open-access] literature' (Schmidt and Jongman 1988:180). Most of the documents involved in these studies are open-access and neither classified nor accessed via government archives: just 4.3 percent (N = 20) of the 463 articles reviewed included an archived source.⁶ While many more included

⁵ Document here is defined as any written text (Scott 1990) and includes published quantitative data, such as official police data.

⁶ See Author1 and colleagues (2018) for discussion on the paucity of historical research on organised crime.

1 state documents which may be closed - most often law enforcement and judicial documents -
2 the access status of these documents was seldom apparent; and this basic information tells the
3 reader much about the validity of the document.
4

5 Closed/restricted and archival sources can be difficult to access and, time and resource
6 intensive. Historian Marc Trachtenberg (2007:147) has, however, argued that closed/restricted
7 documents - which later become available in government archives - are 'far and away the best'
8 document type. As confidentiality allows authors to express themselves more freely than they
9 would in public they tend to be more reliable and less distorted than open-access documents.
10 Closed/restricted documents are:
11

12 ... generated for a government's own internal purposes, and what would be
13 the point of keeping records if those records were not meant to be accurate?
14 It's just hard to believe that a major goal ... would be to deceive historians
15 thirty years later ... you can be reasonably sure that it's not a pure fabrication
16 (Trachtenberg 2007:147).
17

18 Of course, any researcher being given access to closed/restricted-documents needs to question
19 why they are being granted access (see Cressey 1967), why these documents survived if others
20 did not and whether they are being shown a representative sample of the available documents
21 (Scott 1990).
22

23 There are a number of advantages to secondary data analysis. First, documents can be superior
24 to other methods when investigating the past, if subjected to systematic scrutiny, for they
25 represent the 'traces which have been left by the thoughts and actions of' the author without
26 the limitations of hindsight (Langloid and Seignobos 1908:17; also Scott 1990). Second,
27 document research and literature reviews can be cheaper, easier and less risky than primary
28 data collection. Consequently, secondary data analysis is often used to research topics that are
29 particularly difficult to gather primary data on. Its dominance in organised crime research is,
30 therefore, not overly surprising. Third, document research can be valuable in establishing the
31 wider context in which a phenomenon is occurring, in illustrating the potential complexity of
32 the various factors that may be involved and establishing a foundation for future empirical
33 research. Finally, documents can provide important 'verifiable supplementary materials to
34 evaluate and interpret more accurately' data generated by other methods such as interviews and
35 participant observation (Bernasco 2010:3).

As with all methods, there are disadvantages. In order to illustrate some of these limitations, the following section will consider the case of information gathered through media sources, the second most common source in organised crime research. As state-generated data is created through both secondary and primary data collection methods, this will also be discussed at length below.

Media and news stories as a data source

Documents from the media can be useful. Quality investigative journalism can produce very good and reliable data (Rawlinson 2008) on issues and in areas which academics may find hard to access, while news journalism provides the ‘only continuous public source of information about essentially secret subjects’ (Fijnaut 1989:77). As crime news is often based on police or court press releases, or underworld informants, it can represent a convenient conduit between the researcher and underworld or criminal justice system (Fijnaut 1989).

Nevertheless, there are three main concerns with research that draws heavily from media sources. The first is accuracy. News media reports tend to ‘produce a very superficial and very selective image’ (Fijnaut 1989:81). It is well established that even reputable media outlets frequently make factual errors in their reports, not to mention unintentional technical errors and the promotion of propaganda (McDonald and Tipton 1993:191). The news media can also be heavily influenced by works of fiction and, use familiar terms and images which may not be a true reflection (Antonopoulos 2008).⁷

The second issue is bias. Media reports rarely aim to be entirely neutral on any subject. Consequently, an element of distortion enters the coverage of any event or phenomenon. This distortion may reflect the commercial, cultural or ideological preferences and objectives of the proprietor, editor, journalist or even photographer. Distortion can also arise because of the need to compress a story into the available space and publish ‘newsworthy’ stories (see Jewkes 2004). For example, feuds between drugs dealing gangs are often over-reported due to their newsworthiness (actors are often given catchy nicknames, such as the General or Ice Man), while non-commercial and non-violent drug dealers are seldom given space in national or even

⁷ For example, while writing the first draft of this article, a murder in one of the author’s home towns was linked to both the ‘Polish mafia’ and ‘Russian mafia’ by some newspapers, even though there was little justification and the notion was quickly rejected by the authorities.

1 local newspapers. This can skew the perception of drugs markets as overly violent. Distortions
2 may also result from the journalists' increasing reliance on press releases from governmental
3 and intergovernmental bodies, and reciprocal relationships between the media and state. This
4 can result in newspapers echoing official versions of events (Reiner 2000). As such, as
5 investigative journalism becomes more difficult to conduct, and consequently less common,
6 the usefulness of media reports may be declining.⁸

10 A third concern with media reports is that of audience context. A researcher's interpretation of
11 an account is a social construct (Erikson 1973) and foreign language, technical terminology or
12 unfamiliar terms, not to mention cultural norms, jokes and irony, may prevent an understanding
13 of what the author was attempting to communicate (Scott 1990). In short, if the researcher is
14 out of this loop, then serious misinterpretations and misapprehensions can be made (Author2
15 2000). Overall, while the media can represent a useful source, it is worth keeping in mind
16 Yvonne Jewkes (2004:37) warning that the 'media is not a window on the world, but a prism
17 subtly blending and distorting our picture of reality'.

20 These are just some of the concerns with a reliance on media reports, but the same problems
21 are inherent in documents created by state bodies, non-governmental organisations, private
22 sector organisations and, organised criminals and groups (a particularly useful document
23 source seldom used by organised crime researchers, see Figure 2). As a result, there are
24 concerns over the reliability and validity of research that depends heavily on such sources.

26 Some of the issues inherent in using documents can, however, be lessened by following the
27 'quality control criteria' developed by Scott (1990) to assess authenticity, credibility and
28 meaning, coupled with Langlois and Seignobos's (1904) criteria to identify distortions, and by
29 triangulating documents from multiple sources (Author1 2016). Many of the studies reviewed
30 for this paper may well have critically assessed the documents they used and compared multiple
31 data sources, however, there is no way to tell as few papers employing secondary document
32 research included a methodology.

33 **Primary sources**

34 ⁸ See Densley (2018) for a discussion on the usefulness of investigative journalism in
35 countering organised crime.

As Figure 3 indicates interviews are the most common primary data collection method, followed by participant observation, surveys and focus groups. The following section will discuss the strengths and limitations of interviews and the participant observation.

>>>>>> INSERT FIGURE THREE ABOUT HERE <<<<<<<

Participant observation

Participant observation is a method of data collected involving the researchers' observation of phenomena. This can range from shallower field work observations to in-depth ethnography whereby the researcher immerses themselves in their surroundings. The strength of participant observation is that it can provide a level of detail and nuance about an area, crime or group, within a broad social and cultural context, which may be missing in other data collection methods. Furthermore, by exploring the participants' perspective, participant observation can humanise offenders and victims. The method has led to the establishment of typologies, which have then informed studies using other methods, and resulted in the collection of quantifiable data.⁹ The primary weaknesses of participant observation are that, as a case study, it tends not be generalizable or replicable (see Antonopoulos 2008; Hobbs 2000; Hobbs and Antonopoulos 2014; Ritter 2006), immersion in the field and humanisation of participants can weaken researchers' objectivity (Hobbs and Antonopoulos 2014) and the presence of the researcher can change the situation being observed. The limitations inherent in interviews (discussed below) also tend to apply to participant observation.

While organised crime research has a well-recognised tradition of participant observation, originating with Thrasher (1927) and other early Chicago School researchers, this review supports von Lampe's (2012, 2017) observation that the method is actually infrequently used in organised crime research: just 5.6 percent (N = 26) of total articles mentioned some form of participant observation (Figure 2) and the method was used in 16 percent (N = 26) of articles which collected primary data (Figure 3). Moreover, just 50 percent (N = 13) of these articles involved observations of offenders and few directly observed offences. That researchers seldom witness actual crimes is not surprising considering the risk posed to both the researcher and participant (i.e. the researcher becomes both a potential witness to be called before court

⁹ For example, Lisa Maher's (1997) ethnography of Australian drug markets generated quantitative data on price and purity of drugs, while Sudhir Venkatesh was given access to data on a gangs illicit enterprise profits (Levitt and Venkatesh 2000).

and an accomplice who could be prosecuted). The research objective is, however, often to observe the lived experiences and social processes around the crime and then use interviews to extract data on the offence itself.

This said, it is likely that the growing trend towards virtual ethnography will result in an upsurge in participant observation studies of organised crime. This method reduces some of the resource costs and risks associated with traditional participant observation. Further, the anonymity provided by the internet, especially via the 'dark web', may ease some of the concerns offenders and victims have about participating in research with academics from outside of their social network.

Interviewing

Of the 160 articles which used primary data, 79 percent (N = 127) included at least one interview (Figure 3). Of the total 463 articles reviewed, researchers interviewed a combination of: state officials (17.92 percent, N = 83), non-state actors (12.5 percent, N = 58),¹⁰ offenders (9.5 percent, N = 44) and victims (1.07 percent, N = 5) (Figure 2).

This does not, however, mean that the article was primarily based on interviews, but rather that the researchers had conducted some interviewing in an effort to gather information. Several of these articles used interviews not as the main source of data but to supplement other sources, such as documents. This is often apparent in articles where interviews were referenced as footnotes and basic methodological information was absent.

In general, samples sizes are reasonable. Of the 70 articles which provided participant numbers, the median sample size was 47.¹¹ However, 35.7 percent (N = 25) had less than 20 participants and 61.4 percent (N = 43) had less than 40 participants (see Figure 4). This is not particularly worrying: relatively modest numbers are to be expected in organised crime research and even very small samples can be fruitful (i.e. Sutherland 1937).

Of greater concern is that 34.6 percent (N = 44) of studies containing interviews failed to specify participant numbers and 62.2 percent (N = 79) failed to state whether the interviews

¹⁰ Interviews with non-state actors included the public, non-governmental organisations, for profit organisations and academics. Non-governmental organisations were by far the most heavily represented.

¹¹ We have chosen here to exclude single interviews with other researchers, of which there were eight. If these are included, then the median drops to 41.5.

were conducted in a structured, semi-structured or unstructured manner. One of the key tenants of quality research is that future researchers should be able to replicate the study. Replication is impossible without basic information on the number of participants and interview method. Some argue that qualitative studies are un-replicable, due to the individual people's uniqueness, and do not need to be replicable due to being interpretative rather than explanatory. Even if this position is accurate, it remains difficult to assess the quality of the information provided when such basic methodological information is absent.

>>>>>>>>>> INSERT FIGURE FOUR ABOUT HERE <<<<<<<<<<<

There are a number of advantages to using interviews as a way of gathering data. First, it is a very flexible method, especially in the unstructured or semi-structured form that dominates organised crime interviews. This allows interviewers to probe for additional information when interesting or unexpected avenues emerge. Second, interviews provide the researcher with a good measure of control. They can ensure that full answers are provided to specific questions; and if answers are not forthcoming, the researchers can judge whether avoidance of the question is a deliberate decision on the part of the respondent rather than an oversight. Interviews also tend to have good response rates and can produce a great deal of extra and unanticipated information. Indeed, supplementary information gathered in interviews can be valuable in establishing wider context and, can result in exciting avenues for future research and analysis.

Again, however, there are disadvantages. First, interviewing is an expensive method both in terms of finance and time, and, unless supported by large grants, researchers are usually severely limited in the number of interviews they can conduct: a problem exacerbated by the difficult target populations organised crime researchers must contend with and by the fact that organised crime researchers tend to work alone. Second, there is a risk of interviewer bias entering the data. The flexibility of interviews allows room for the interviewer's personal influence and bias. For example, the way a particular question is phrased can influence the type of answer the respondent gives, as can the location, the interviewer's skill and experience, and the recruitment method. The result is that the same individual, when interviewed by two different researchers about the same topic, could provide noticeably different answers. Indeed, the same researcher interviewing the same participant on different days may get noticeably different answers.

1 A third issue, common to all methods discussed above, relates to truthfulness and the validity
2 of participant accounts. Wim Bernasco (2010:5) suggests that offenders 'lie or misrepresent
3 information' for a 'myriad of reasons'.¹² Henk Elffers (2010:14) proposes three broad 'validity
4 threats':
5
6

- 7 1. Misinformation - participants pass on information they do not have access to because
8 they are not well informed, did not observe the event or have memory problems;
9
- 10 2. Misunderstanding - the meaning of the question or answer is lost during the interview;¹³
11
- 12 3. Misleading - the participant misleads the researcher by 'knowingly returning an
13 incorrect answer' (Elffers 2010:14), possible by giving replies which they think will
14 please or not offend the interviewer, including exaggeration or downplaying of criminal
15 activities.
16
17
18
19
20

21 This said, a benefit of interviewing is that the researcher can use tried and tested techniques to
22 identify threats to validity, such as repeat interviews, participant observation and, triangulation
23 with other participants and sources. Indeed, as Clifford Shaw (1930; cited in Bernasco 2010)
24 observed, distortions can even provide important information if recorded and classified as such.
25
26

27 A further problem with interviews in organised crime research is that most studies employ
28 opportunity sampling: many use pre-existing contacts or are referred to participants through
29 information provided by law enforcement (von Lampe 2012, 2017), and then employ
30 snowballing (Hobbs and Antonopoulos 2014). This means that the interviews are carried out
31 with conveniently available groups or individuals with no systematic sampling. This is not
32 entirely surprising: opportunity sampling is common when dealing with difficult to access
33 groups or individuals and may often be the only option. This sampling method does, however,
34 pose serious limits to the generalizability of findings to wider populations (Burns 2000:93). It
35 can be difficult for researchers to know if they are dealing with biased samples that are
36 noticeably different from the population of interest. The sample may be representative, but then
37 again it may not. A consequence of this uncertainty, is that opportunity sampling tends to be
38 limited to more exploratory and descriptive research in the social sciences. The dominance of
39

the method in organised crime research, may therefore, raise a question mark over the reliability of the information being generated.

State-generated data

>>>>>>>>> INSERT FIGURE FIVE ABOUT HERE <<<<<<<<<<

Figures 5 is a redrawing of Figure 2 to highlight our fields overreliance on data collected from state agencies.¹⁴ The influence of the state increases when we consider that 41.4 percent (N = 192) of papers used data collected from media sources and that many media sources are reliant upon press releases from the police and other state bodies (Reiner 2000). This can be compared with the offender perspective: just 9.5 percent (N = 44) of all papers interviewed an offender, 1.07 (N = 5) interviewed a victim, and 0.43 (N = 2) surveyed victims. To put this in stark perspective, more papers contained no sources than interviewed or surveyed victims. In short, while the state and media have a significant voice in organised crime research, the offender voice is hushed and victims are all but silent.

Interviewing and observing offenders is useful as they are viewed by many as being the most knowledgeable informants (Zhang 2010) with ‘the richest source of information on their crimes and on their lives’ (Bernasco 2010:3). There can be little doubt either that the victim is able to provide the richest source of information on their lived experience of being victimised.

The difficulties of recruiting offenders to participant in research is often seen as a key reason for the dominance of state data (Zhang 2010). While victims are seen as even more ‘reluctant to talk to researchers’ (Hobbs and Antonopoulos 2014:96), some studies on human trafficking (see Kim et al. 2009; Tsutsumi et al. 2008) and terrorism (see Argomaniz and Lynch 2014) have interviewed or surveyed victims.

There are issues with using data generated by the state, whether gathered second-hand through documents or first-hand by interviews and surveys. First, some data is restricted to those with ‘connections’, notably researchers on government funded research (Cressey 1967) or those ‘well-respected’ by law enforcement or other state agencies (Fijnaut 1989). Second, state data can be limited by partiality (Hobbs 2000). For example, data and intelligence reports on drug production and trafficking have been manipulated to highlight the success of a programme or policy, to show increased trafficking in order to attract foreign aid and for diplomatic

¹⁴ For ease, state here includes intergovernmental organisations, such as UN bodies who are reliant upon data provided to them by member states.

objectives, such as undermining an enemy on the international stage (Author1 2016). Closer to home, governments have - often alongside the media - perpetuated alien conspiracy myths to deflect attention from their own failing policies (Gallhier and Cain 1974; Hobbs and Antonopoulos 2013). Related to this, law enforcement case files, a common source, are 'rhetorical devices' whose primary purpose is to secure conviction in court. As such, they tend to project an image of

... the one-dimensional "criminal" and feed the notion of an underworld of exclusively deviant intent, driven by economic motivation, yet drained of cultural context (Hobbs and Antonopoulos 2014:99).

Third, there are often gaps between police intelligence and organised crime realities (Author1& 2015). Law enforcement and other state employees perception of events can be influenced by the media (Decker and Kempf-Leonard 1991), political rhetoric (Author1& 2015) or may view the world from their own institutional and cultural viewpoint (Hallsworth and Young 2008; Author1& 2015).

Fourth, Elfers (2010) three validity threats, discussed above, apply as much too state employees as they do offenders and 'neither the reliability nor validity of what is said [by state employees] ... should be taken for granted' (Fijnaut 1989:80). Most practitioners, no matter how informed, only have a partial picture of the phenomena through fragmented experiences and there will often be elements of the picture they are unable or unwilling to disclose. Furthermore, law enforcement data can itself represent second-hand information from informants who may or may not have witnessed the event: The informant may be selective in what she tells the officer, who may be selective in what she tells the researchers or puts in the records to be read by the researcher.

The result of this overreliance on media and state sources can be the prolongation and dissemination of 'unchecked folklore regarding organized crime' (Gallhier and Cain 1974:73) and the employment of 'politically motivated' and 'constantly shifting' conceptions of which activities are to be included as organised crime (Hobbs and Antonopoulos 2014:98). Whereas, what:

... is needed [of organised crime research], or at least appears to be desirable, is a concerted effort by interested scholars to confront media and politically induced imagery with well researched and sober analyses (von Lampe 2002:189).

Overall, Figure 1 shows that researchers are very heavily dependent on easily accessible sources of data and only about 34.5 percent (N = 160) of articles provide substantially new knowledge which was previously unavailable to the field. Even when serious concerns exist with the manner in which data is collected, researchers can still take steps to address this when they progress to analysing the gathered data, and it is to this issue that the focus of this article now turns.

Analysing the data

From the 1950s, all social science disciplines experienced a rapid increase in the use of statistics. As people and groups of people are extremely complex, social science researchers typically have to work with very 'noisy' data where there are potentially a vast number of factors exerting an influence on any one behaviour, event or trend. Statistical analysis has emerged as a way for researchers to determine which factors genuinely are important and which are less so.

Descriptive statistics enable the researcher to summarize and organize data in an effective and meaningful way. Inferential statistics allow the researcher to make decisions or inferences by interpreting data patterns. Inferential statistics are regarded as particularly valuable as they introduce an element of control into research that can help to compensate for the use of relatively weak data collection methods. Moreover, inferential statistics provide an indication of how confident we should be that our results were not arrived at by chance, or methodological error, and whether they are important (statistically significant) or not. This provides insight into the generalisability and representativeness of our findings (Frankfort-Nachmias and Nachmias 1996).

Experimental designs are often identified as particularly powerful. Here control is normally achieved by randomly assigning research subjects to experimental and control groups. This can, however, often be very difficult to achieve in real-world research, and consequently the lack of control throws doubt on any association between variables which the research claims to find. Inferential statistics can help to introduce a recognized element of control, so that there is less doubt and more confidence over the veracity of findings (Frankfort-Nachmias and Nachmias 1996).

Figures 2 and 3 show that even though organised crime researchers tend to rely heavily on uncontrolled data-gathering methods – secondary document analysis, unsystematic interviews

and participant observation - very little effort has been made to balance this by the use of statistical analysis.

>>>>>>>>> INSERT FIGURE SIX ABOUT HERE <<<<<<<<<<

Figure 6 puts the trend seen in Figures 2 and 3 in a solemn context. It shows that from 2004 to 2018 just under 10 percent (N = 43) of research papers in the two primary organised crime journals involved the use of inferential analysis; and just under 70 percent (N = 322) had no statistical analysis of any type.

This article is not arguing that statistical analysis is superior to qualitative research, nor that it should dominate the field or feature in most piece of organised crime research. Rather we argue that, as it appears that organised crime research suffers a serious qualitative imbalance, greater effort is needed to address this imbalance. Statistics alone are not the way forward, but neither is avoiding their use to the degree that organised crime research apparently does. Indeed, the most effective, well-rounded and influential studies will often involve a mix of qualitative and quantitative analysis. Furthermore, research is an iterative process and qualitative methods can be productively employed to better understand and further explore quantitative results, and vice versa. For example, Elija Anderson's (2000) 'code of the street', a theory derived from ethnography, has been subjected to a great deal of quantitative testing and exploration.¹⁵

Of course, raw statistical data does not come out of thin air. The majority of quantitative articles reviewed here drew data from published official statistics. The limitations of official crime data are well documented (Bottomley and Pease 1994) and criminologists often propose victimisation surveys as a corrective. Although there are issues here also. For example, surveys often miss hidden populations (including those individuals most vulnerable to exploitation by organised crime) and the flexibility of the term organised crime can result in a lack of awareness by participants about whether they have been the victim of 'organised crime' or not (Hobbs and Antonopoulos 2014). Indeed, the local drug wholesaler or hard-man extorting businesses may not a fit the public perception of predatory thugs in dark suits 'whacking' their rivals.

¹⁵ In some respects, this challenges the critique that single case studies are not generalizable: the single case study may provide a foundation for comparison with future qualitative and/or qualitative studies on the same topic with different samples; and the more studies which are undertaken the more we are able to generalise findings.

1 While there are challenges in conducting victimisation surveys of organised crime, that the
2 method has seldom been employed in organised crime research (for an exception see Tilley
3 and Hopkin 2008) represents a cavernous hole in our knowledgebase.
4

5 **Conclusion**

6
7
8 It is difficult not to be pessimistic when presented with the above data. Some of the
9 observations by Cressey (1967:102) are as relevant today as they were 50 years ago:
10

11
12 Social scientists have tended to write about organized crime only in
13 descriptive terms, taking their clues from the reports on Congressional
14 hearings, rather than in analytical terms.
15
16

17
18 On a more positive note, we can contest Cressey's (1967:102) suggestion that the study of
19 organized crime requires 'methods not ordinarily utilized by social scientists'. The 160 papers
20 which collected new data reviewed here used the full range of social science data collection
21 and analysis methods. The question now is not whether typical methods can be utilized but
22 rather why are some so rarely utilized?
23
24

25
26 From this review we can identify a number of key issues limiting organised crime research.
27
28 First, while organised crime researchers have used a considerable range of data collection
29 methods and sources, secondary analysis of open-access documents has overwhelmingly
30 dominated the field. In addition, data analysis has been predominantly qualitative. The lack of
31 statistical analysis may partly reflect both the absence of primary survey data collection and,
32 the paucity and weakness of official statistical data on organised crime.
33
34

35
36 The second, and most damning limitation, is the overuse of data from the state and media, and
37 underuse of offender and victim perspectives. The result is a field lacking balance, which
38 appears to 'obediently follow the beaten track of popular imaginary and official parlance' (von
39 Lampe, 2012:192). This is not to say that we should not interview state officials or use state
40 documents and data. Indeed, many classic and scientifically rigorous studies have relied
41 partially or solely on official sources: some of the strongest studies have triangulated accounts
42 from a range of perspectives.¹⁶ Nevertheless, for the field to thrive it must balance the official
43
44

45
46
47
48
49
50
51
52
53
54 ¹⁶ Felbab-Brown (2014) suggests that interviewing government officials, NGO workers and
55 journalists prior to conducting fieldwork not only creates a contextual foundation which
56 informs interviews with offenders but can also be invaluable for preparing logistical and
57 security arrangements, including knowing which areas to avoid.
58
59
60
61
62
63
64
65

1 and media version of events with that of offenders and victims. In particular, the distinct lack
2 of victimisation surveys may be the most pressing concern here.

3
4 Third, the field appears somewhat lackadaisical about scientific rigour. This is most apparent
5 in the lack of a described methodology in over half of all published papers, coupled with the
6 failure to elucidate interview type for the majority of studies involving some interviews, and
7 the failure to specify the number of participants for many more. The lack of basic
8 methodological discussion prevents readers from critically assessing the validity of the research
9 or hinders attempts to replicate the study.

10
11 This article is not lobbying for any one method of data collection or analysis. A healthy field
12 will employ a wide range of methods, both qualitative and quantitative. Nor is it trying to
13 minimise the scholarly importance of document research or state-generated data (both authors
14 have used these sources in their own work). Equally, empirical research or inferential statistics
15 are not markers for success: poorly designed and executed research contributes little to the
16 knowledgebase, and could produce unintended negative consequences. Our findings are not
17 critical of any one published article, but rather of a field of research which when considered en
18 masse appears unbalanced by a reliance upon a small number of methods and sources.
19 Rebalancing the field requires more organised crime researchers to speak to offenders and
20 victims, to employ greater use of statistical analysis and to apply more rigour to our
21 methodologies.
